I travel and I camp quite a lot. And I love astrophotography. How can you mix these two? Some time ago, I was using a traditional German equatorial mount, a guidescope and a laptop for astrophotography. The mount was around 18 kilos, tripod included, the guidescope around 2 and the laptop added another 1.5 kg to the setup. This was without my camera and imaging telescope or camera lenses. Oh ...

This is a simple rule to minimize unwanted star trails in your astrophotography. The basic idea is: 500 divided by the focal length of your lens = The longest exposure (in Seconds) before stars start to "Trail". For example, if our focal length was 24mm then our longest exposure would be (500/24) 20.8 seconds.

CMOS cameras have become more popular in astrophotography over the past few years. Having started out as high-speed planetary imaging cameras they're increasingly being used for deep-sky imaging by amateur astrophotographers. Now we are seeing fully cooled cameras and full-frame sensors arriving on the market.

Astrophotography involves some really long exposures. In daytime photography, a 5-second exposure using a filter, low ISO, and f/22 can create some incredible landscape images. This can capture movement such as flowing water and passing clouds. In astrophotography, we use ultra-long exposures to capture dim objects in space.
