Last Modified Date: August 26, 2020. "Directional solidification" is a metal casting term. It refers to the process of controlled feeding of the molten metal into a temperature-controlled mold to produce a part that is free of hollow spots, called shrink defects. Directional solidification is also used to refine the metal during the casting process because the impurities found in the molten metal will continue to rise to the surface of the pool, following the path of least resistance as they ...

Directional solidification (DS) and progressive solidification are types of solidification within castings. Directional solidification is solidification that occurs from farthest end of the casting and works its way towards the sprue. Progressive solidification, also known as parallel solidification, is solidification that starts at the walls of the casting and progresses perpendicularly from that

The side feeder attached so that the casting is in the drag, as shown in the lowest diagram in Figure 5.20, produces favourable directional solidification. The influence of using a tapered feeder with the two acceptable systems in Figure 5.20 is shown in Figure 5.21. In both cases the final freezing position is moved closer to the feeder contact location.
